Pre & Postharvest Disease Management Workshop

March 4th, 2020

Module I

Part 1: Overview and Occurrence of Major Postharvest Diseases

Kutay Ozturk and Achour Amiri, WSU Plant Pathology

Learning Objectives

- Acquire knowledge **about the most important pathogens** causing fruit rots
- Know their occurrence in Washington and the Pacific Northwest
- Better understand how these pathogens infect fruit
- **Identify key diseases**
- Acquire knowledge about **quarantine** pathogens

Pre & Postharvest Disease Management Workshop

Quiz

1- How many fungal pathogens are reported to cause decay on pome fruit?

- ☐ 12
- ☐ 38
- ☒ 100
- ☐ 312

2- How many of these 100 cause economic losses?

- ☐ 3
- ☒ 10
- ☐ 19
- ☐ 51

Blue Mold:
Penicillium
expansum,
Penicillium
spp.

1. **Major threat:** # 1 disease ~\$5M annual loss

2. Airborne & wound-pathogen

3. **Soft tan to light brown** lesion with green spore masses

4. Some species: Pharmaceutical and food industries

5. Mycotoxin in processed apples & pear

Gray Mold:

Botrytis cinerea,
Botrytis mali?

1. **Big threat:** # 2: apples, # 1 or 2: pear

2. Latent and wound-pathogen

3. Survives in mummies and organic matter

4. **Spongy brown lesion-gray** mycelium

5. Nests in storage bins

Speck & Phacidiopycnis rot

Phacidiopycnis washingtonensis, *P. pyri*

1. **Emerging threats:** # 3 or 4 for loss
2. *P. washingtonensis* (Apple) and *P. pyri* (Pear)
3. Calyx-stem ends, and wound-pathogens
4. Survives on crabapples, cankers, dead twigs
5. **Firm lesion** with specks, or water-soaked margins, black tissue as decay advances
6. **Quarantine** in some countries e.g. China

Bull's eye rot

Neofabraea
spp.

1. **Challenging**: # 3 or 4 for losses
2. Four species: *Neofabraea perennans*, *N. malicorticis*, *N. alba*, *N. kienholzii*
3. Infections through lenticels and stem-bowl
4. Cause anthracnose and perennial cankers on trees: overwinters
5. **Brown sunken lesions** with creamy-spores
6. Current cultivars: vary in susceptibility
7. Preharvest rain or wetness increase risks

Mucor rot

*Mucor
pyriformis,
Mucor spp.*

1. **Risky threat:** Ranked # 4 for losses
2. Wound pathogen, survives in soil/bins/dump tanks
3. **Causes a very soft juicy brown** lesion
4. **None** of current fungicides are effective
5. Does not nest in storage bins but can break (too soft) and spread easily

**Other
secondary
diseases**

Lambertella rot*

Alternaria rot

* Quarantine

Sphaeropsis rot*

Nectria rot *

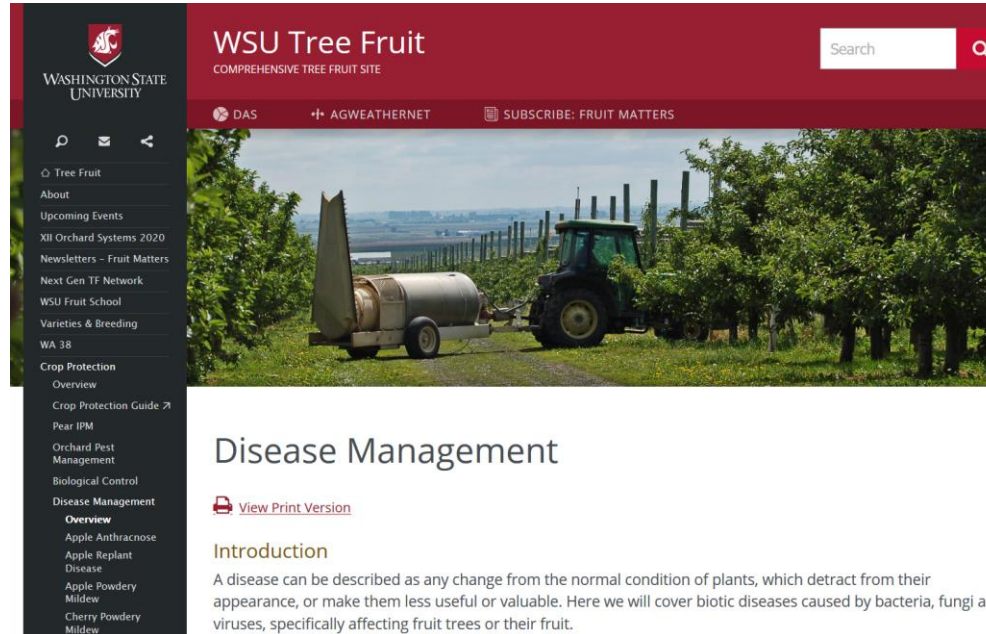

Summary

- About 100 fungi can infect pome fruit
- About 10 pathogens can cause economic losses
- **Blue mold** and **Gray mold** are the two most important postharvest rots
- Three **quarantine** pathogens may be of concern at export
- Apple and pear processors should be aware of potential **mycotoxin**-related issues

Additional sources

- Factsheets provided in the packet

WSU Tree Fruit Extension

GOOD FRUIT CROWNS

Postharvest Diseases

Blister Spot
(Pseudomonas syringae)

Blue Mold
(Penicillium expansum)

Symptoms Dark dotted, brown to black blisters centered around lenticels typically located on the upper half of the fruit. The lenticel itself remains unaffected by may appear raised. Fruit infected by bacteria preharvest; may progress very slowly during storage.

Possible confusion Lenticel breakdown and Bitter pit. Blue lenticel breakdown, blister spot may already be present at harvest. The lenticels are not sunken, and in most cases appear raised.

Varieties affected Musta and Golden Delicious; pictured on Gala.

Symptoms Symptoms include a soft, watery lesion with a sharp margin. Tissue colonized by the fungus is light tan to dark brown and the decayed tissue is easily separable from the healthy tissue, leaving it like a "scooped out bowl". The infection often starts at wound sites. The fungal mycelium is white, but the fruiting bodies (spore masses) may look blue or blue/green. The rot smells earthy and musty, similar to a damp basement.

Possible confusion Early stages of mucor rot. Blue mold can be distinguished by the smell. Non-spore masses, infection is firmer and has irregular lesion margins as opposed to

Varieties affected All varieties. Pictured on Red Delicious (external) and Honeycrisp (external and internal).

Bull's Eye Rot
(Neofabraea spp.)

Gray Mold
(Botrytis cinerea)

Symptoms Characteristic circular lesion that is flat, slightly sunken, light brown to dark brown in color. The center of the lesion is often a lighter color. Spore masses may appear as a white, fuzzy growth. The rot is commonly seen originating from the stem-bowl.

Possible confusion Blue mold and other rots at early developmental stage.

Varieties affected All varieties can be affected. Pictured on Golden Delicious.

Symptoms Decayed tissue is spongy, firm and cannot be easily separated from the healthy tissue. The rot is light brown to dark brown. Gray mold may develop, which may spore masses. The rot is commonly seen originating from the stem-bowl. Spore masses are gray, powdery. Golden Delicious generally does not have characteristic odor.

Possible confusion Phacidiopycnis rot; Sphaeropsis rot

Varieties affected All varieties can be affected. Pictured on Cripps Pink (external; no spores) and Honeycrisp (external and internal).

Mucor Rot
(Mucor piriformis)

Phacidiopycnis Rot
(Phacidiopycnis washingtonensis)

Symptoms Decayed tissue is soft and juicy, and light brown to brown in color. There is a distinct margin between healthy and diseased tissue. Black to dark gray mycelium with dark sporangia can develop. Mucor rot has a sweet odor.

Possible confusion Blue mold.

Varieties affected All varieties can be affected. Pictured on Pink Lady.

Symptoms The rot presents with two symptoms. Flesh infections are spongy to firm, not separable from healthy tissue, and is sometimes visually similar to gray mold. The color of the decayed area is light to dark brown, and black in advanced stages. A second symptom of infection starts at lenticels. Symptoms are brown to black specks with a white to light tan center around the lenticels. Both symptoms appear more often on the calyx and stem end of the fruit.

Possible confusion Blue mold, Gray mold, and other rots at early developmental stage.

Varieties affected All varieties can be affected. Pictured on Golden Delicious.

Sphaeropsis Rot
(Sphaeropsis pyriputrescens)

Sphaeropsis Rot
(Sphaeropsis pyriputrescens)

Symptoms Sphaeropsis rot is firm, brown to dark brown and even black in advanced stages. Decay advances along vascular tissue, turning the tissue brown. White mycelia can form under high humidity, and fruiting bodies (pycnidia) may form in advanced stages. Sphaeropsis rot has a distinct bandage-like odor.

Possible confusion Gray mold.

Varieties affected All varieties can be affected. Pictured on Golden Delicious and Gala.

Module I

Part 2: Inoculum Sources & and Infection Timeline

Learning Objectives

- Notion of **pathogen** versus **disease (decay/rot)**
- **Infection timeline** of fruit by major pathogens
- **Factors** that may exacerbate infections
- Acquire and apply knowledge to **assess and anticipate infection risks**

Economics of fruit decays

\$~3B
\$~0.5B (organic)
\$~4B

\$0.5B

Fruit losses (%)	Economic impact (\$M)
0.1	-4
0.5	-20
1.0	-40
5.0	-~200

Major diseases and their causal pathogens: Pre and postharvest

Disease	Pathogen	Importance in PNW
1. Fire blight	<i>Erwinia amylovora</i>	++++
2. Blue mold	<i>Penicillium expansum</i> , spp.	++++
3. Gray mold	<i>Botrytis cinerea</i>	+++
4. Speck rot	<i>Phacidiopycnis</i> spp.	++
5. Powdery mildew	<i>Podosphaera leucotricha</i>	++
6. Mucor rot	<i>Mucor piriformis</i>	++
7. Bull's eye rot	<i>Neofabraea</i> spp.	++
8. Alternaria rot	<i>Alternaria alternata</i>	++
9. Sphaeropsis rot	<i>Sphaeropsis pyriputrescens</i>	+
10. Yellow rot	<i>Lambertella corni-marisi</i>	+
11. Other Rots	Multiple species	+

Diseases and their causal pathogens: Symptoms vs. Infections

Disease name	Pathogen name	Symptoms visible	Infection occur
1. Fire blight	<i>Erwinia amylovora</i>	Orchard	Orchard
2. Powdery mildew	<i>Podosphaera leucotricha</i>	Orchard	Orchard
3. Gray mold	<i>Botrytis cinerea</i>	Warehouse	Orchard
4. Speck rot	<i>Phacidiopycnis spp.</i>	Warehouse	Orchard

9. Mucor rot	<i>Mucor piriformis</i>	Warehouse	Warehouse*
10. Blue mold	<i>Penicillium expansum</i>	Warehouse	Warehouse*

Marginal infections may occur close to harvest

Pathogens

- Fall & Winter: Where do fungi go?
- Spring: What changes for the pathogens?
- What are the main sources of inoculum?
- How infections start and progress during the growing season?
- What **Factors** may exacerbate infections?
- How infections progress in cold storage?

How fungi survive in orchards ?

Normal conditions

Spores & Mycelia

Organic matter, free water, mummies, cankers

Harsh conditions

Sclerotia

Sexual reproduction

Fruiting bodies

Rare

What happens to pome fruit pathogens in fall and winter?

Most pathogens undergo a **dormancy**:

1. In **buds** (Mildew)
2. As **sclerotia** (Botrytis-Gray mold, Alternaria)
3. **Cankers**, dead wood, **dead twigs**, **mummies**, **crabapples**, organic matter: *Neofabraea* (bull's eye rot), *Phacidiopycnis*, *Sphaeropsis*

What happens to pome fruit pathogens in **spring** and **summer**?

Fungi require three main factors to cause infections

		Conditions in Central WA during	
Factor	Range	Spring	Summer
Temperature	Min-Optimal-Max	Mostly Optimal	May limit some fungi >90°F
Nutrients	Vary by fungi	Depends on orchard management*	Depends on orchard management
Moisture	Moister the better	Near-optimal	Dry: Disadvantageous ?

* Orchard management: Natural habitats removal: Mummies removal, pruning cankers and crabapples, orchard floor & weed management.

Inoculum sources of major rot pathogens

Disease	Pathogen	Inoculum sources
1. Blue mold	<i>Penicillium expansum</i>	Bins, rooms, flume water, soils
2. Gray mold	<i>Botrytis cinerea</i>	Mummies, dead leaves
3. Speck rot	<i>Phacidiopycnis</i> spp.	Crabapple pollinizers, dead twigs
4. Mucor rot	<i>Mucor piriformis</i>	Soils, dead leaves, bins
5. Bull's eye rot	<i>Neofabraea</i> spp	Cankers, dead wood
6. Alternaria rot	<i>Alternaria alternata</i>	Mummies, dead leaves
7. Sphaeropsis rot	<i>Sphaeropsis pyriputrescens</i>	Cankers, dead wood & bark, dead twigs
8. Yellow rot	<i>Lambertella corni-marais</i>	Unknown, mummies?

Research

Current knowledge about infections caused by some rot pathogens:

- *Botrytis* (Gray mold)
- *Neofabraea* (Bull's eye rot)
- *Phacidiopycnis* (Speck rot)
- *Penicillium* (Blue mold)

Botrytis cinerea (gray mold) infections in the orchard

- Optimal temperature: 20-25°C (68-77°F), Slows down >91°F
- Wetness duration: 6-14 h

How can we use this information to improve management? (Module 2)

Neofabraea spp. (bull's eye rot) infections in the orchard

- Optimal temperature: 20°C (68°F), Slows down >88°F
- Wetness duration: 6 h

Apple cultivars: Vary in their susceptibility to *Neofabraea*, trend may vary but overall similar

Pear cultivars: Not much known but d' Anjou are susceptible

Phacidiopycnis spp. (speck rot) infections in the orchard

- Optimal temperature: 20-25°C (68-77°F), Slows down >93°F
- Wetness duration: 6 h

Apples: Pruning and removing mummies from pollinizers (es. Manchurian crabapples) is key, use other cultivars in new plantings

Pears: Origin still not fully known, **forest trees?**

Penicillium spp. (blue mold) infections from orchard to warehouse

Bin/airborne
populations

Fruit

~~Valid~~
relationship

Key timing of pathogen infections in the orchard

Podosphaera leucotricha (Mildew)

Erwinia amylovora (Fire blight)

Alternaria alternata (Alternaria rot)

Botrytis cinerea (Gray mold)

Neofabraea spp (Bull's eye rot)

Phacidiopycnis spp. (Speck rot)

Sphaeropsis pyriputrescens

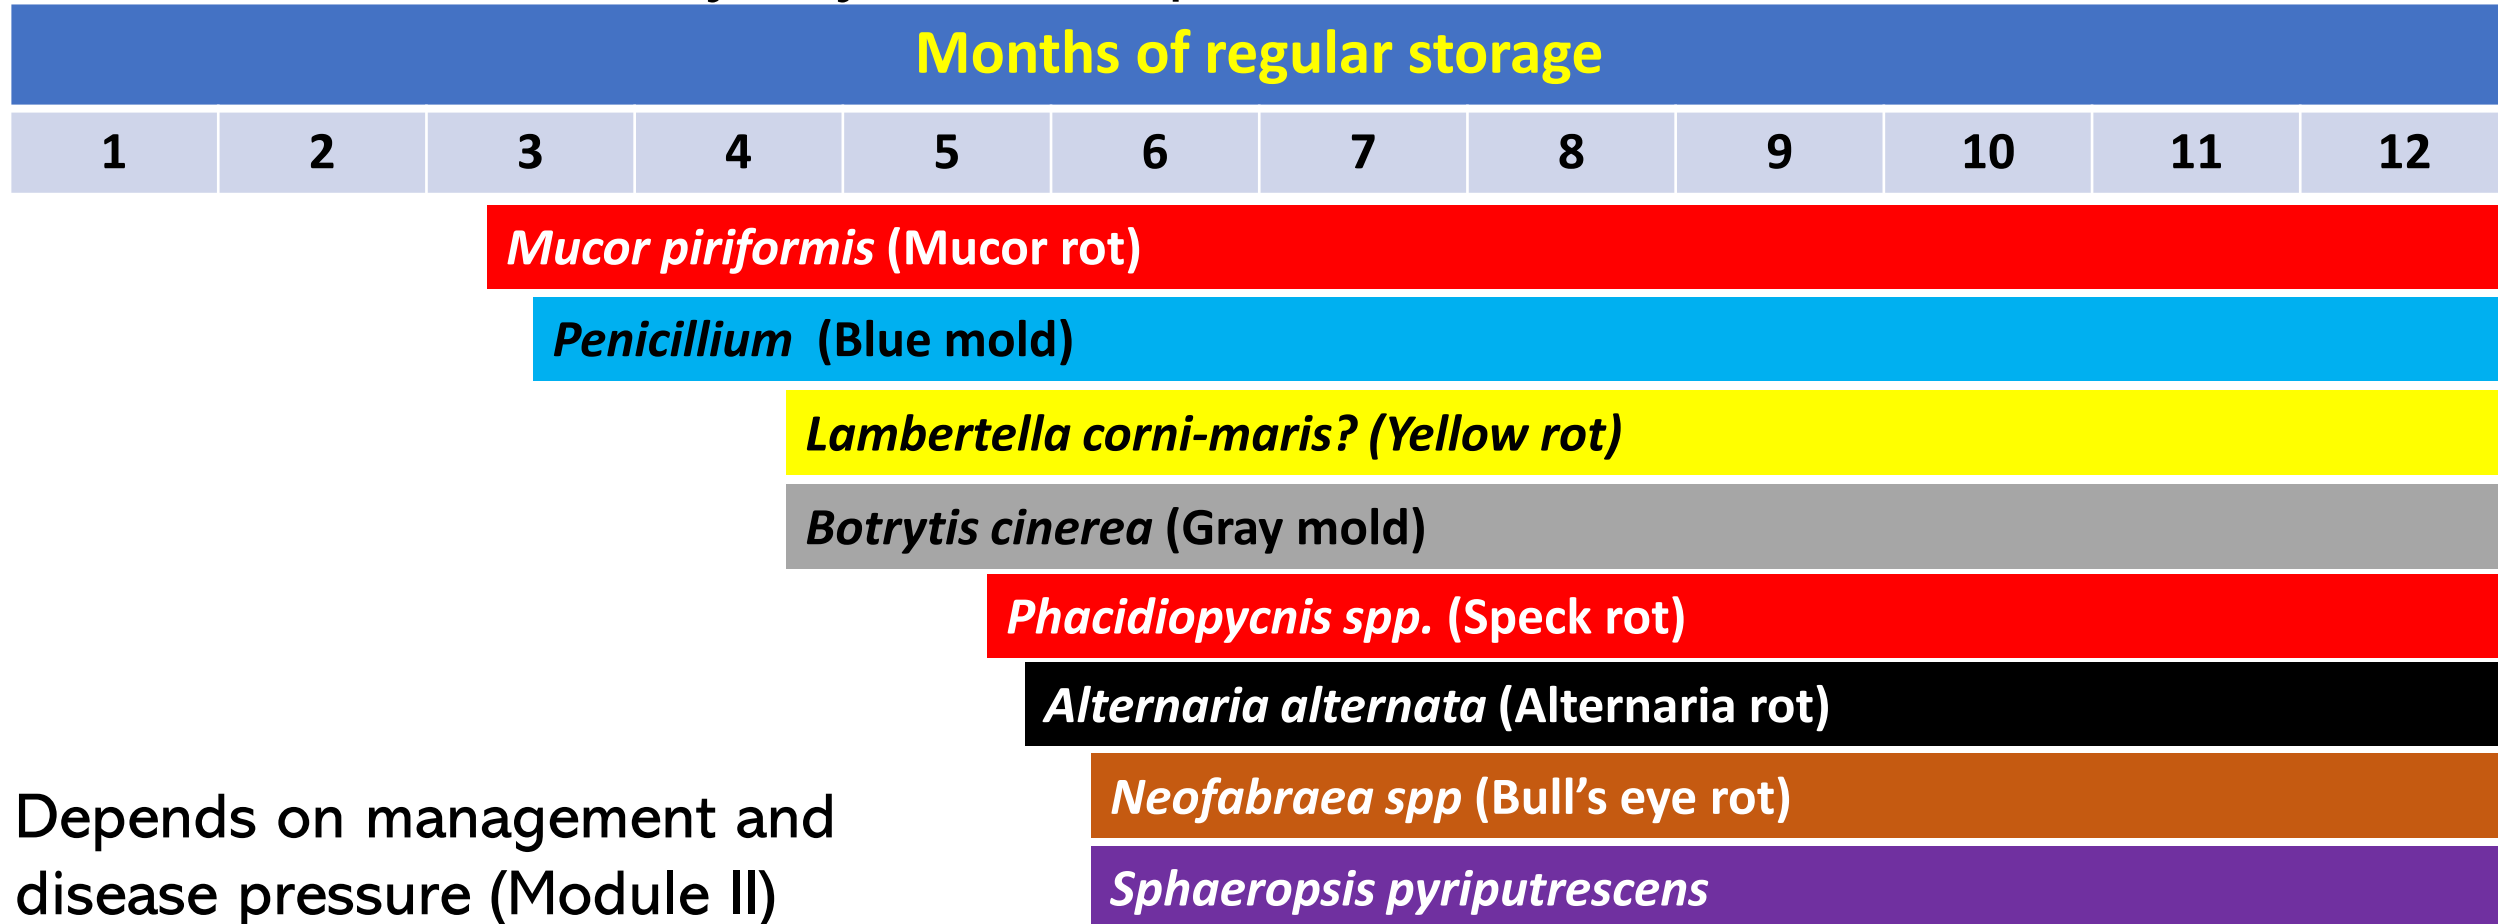

Lambertella c-marisi? (Yellow R)

Penicillium (Blue M)

Mucor piriformis

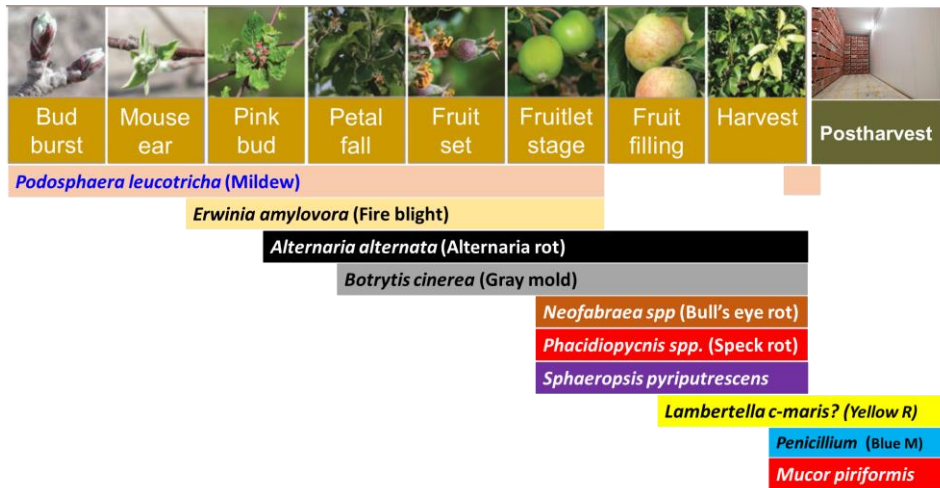

Progress¹ of decays after harvest in regular storage

¹ how fast they may become a problem

Growth in CA or ULO may be slightly further delayed

Relative growth of infections in regular storage

Months of regular storage											
1	2	3	4	5	6	7	8	9	10	11	12
<i>Mucor piriformis</i> (Mucor rot)											
<i>Penicillium</i> (Blue mold)											

Why *Penicillium* and *Mucor* are faster in cold storage although they infect fruit later ?

- **Wound pathogens**: infections progress faster on wounds
- **Inoculum** more available
- Better-**adapted** (**virulent**) to cold temperatures

Infection timeline: bottom-line

If no sanitation & effective sprays in the **previous season**

Inoculum present in spring

If no **timely spring sprays** in the following season

Break the cycle

A **cleaner** fruit at harvest is **less likely** to **decay** in storage

More fruit will carry the inoculum to storage rooms

Infections start in spring and increase as fruit mature

If no **timely summer sprays**

Impact

How is this knowledge beneficial for decay control?

- **Anticipate** when infections are likely to occur
- Know how infections may evolve during the season and in storage: when to expect decay to become a real problem
- Factors that may exacerbate infections
- **To optimize management:** Module II

Summary

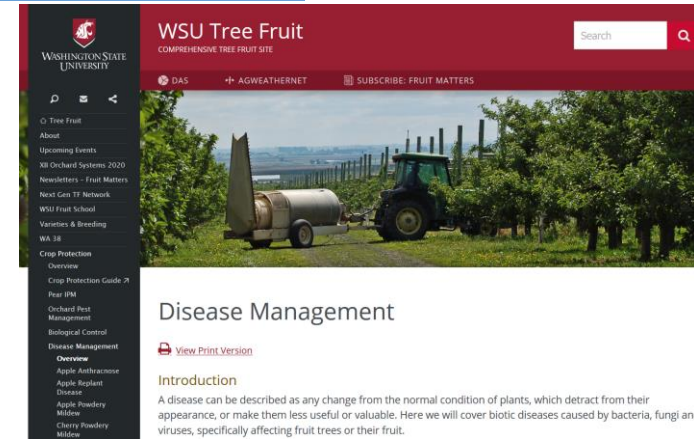

- 80% of pome fruit infections occur in the orchard
- Pathogens survive in different ways in orchards and warehouses
- Pathogens infect fruit at different growth stages
- Infections may slow down in warm weather then pick-up and continue through harvest
- Good sanitation and timely sprays will **break-up infection cycles**
- Cold storage slows down but does not fully stop infections

Pre & Postharvest Disease Management Workshop

Jonagold	5	4	6	4	2
Royal Gala	2	3	6	1	4
Granny Smith	3	3	4	6	6

Long term goal = resistance to postharvest diseases

Resistance genes to blue mold

- Wild apple: *Malus sierversii* (central Asia)
- Ongoing research (USDA-ARS-East Coast)

Optimized Disease Management **SHOULD** include:

1. **Appropriate** preharvest cultural practices
2. **Appropriate** preharvest spray program
3. **Timely** preharvest sprays
4. **Appropriate** postharvest sanitation practices
5. **Appropriate** postharvest fungicides

How much inoculum (spores) you have in the orchard is a big factor for your risk of infection!

Risk of gray mold

Preharvest fungicide	Preharvest rain	Orchard condition		
		Good	Average	Poor
Yes	No	Low	Low	Moderate
Yes	Yes	Low	Moderate	High
No	No	Low	Moderate	High
No	Yes	Moderate	High	Extreme

Preharvest management Overhead Irrigation/ Cooling

- Adds moisture and spreads spores
- Consider the risks
- Plan your sprays around it
- Consider netting
- Cycle cooling to avoid long wet periods

Preharvest Chemical control

1. What are the most effective preharvest fungicides?
2. How many times should I spray in the orchard?
3. What the best time to apply preharvest sprays

- **22 Preharvest fungicides**
 - **19 single-site**
 - **3 multi-site (Captan, Ziram, Sulfur)**
- **5 Postharvest fungicides**
 - **4 single-site**
 - **1 multi-site (Captan)**

Past & current approach?

Mildew Sprays

Rots

Which way to go?

- **Most common approach**
 - Bins are set in orchards 2-4 weeks before harvest
 - Limit access to orchards for sprays
 - One Spray: 30-0 Days preharvest ?

Module I-Part 2

- Pathogens present in orchards
- Infections may occur anytime between bloom & harvest
- Fruit more susceptible closer to harvest

Is there an optimal spray number and better time(s) for applications?

Key timings of pathogen infections in the orchard

Podosphaera leucotricha (Mildew)

Erwinia amylovora (Fire blight)

Alternaria alternata (Alternaria rot)

Botrytis cinerea (Gray mold)

Neofabraea spp (Bull's eye rot)

Phacidiopycnis spp. (Speck rot)

Sphaeropsis pyriputrescens

Lambertella c-marisi? (Yellow R)

Penicillium (Blue M)

Mucor piriformis

Number and timing of applications

Bloom-Petal fall (PF)

F. set-Fruitlet

PF + 45 d

14-0 DPH

Option A

4 preharvest sprays

F. set-Fruitlet

PF + 45 d

14-0 DPH

Option B

3 preharvest sprays

Which fungicide to spray? - Example

							
Bud burst	Mouse ear	Pink bud (white bud)	Petal fall	Fruit set	Fruitlet	Fruit filling to maturity	Harvest
			Bloom-Petal fall (PF)	F. set-Fruitlet	PF + 45 d	14-0 DPH	
			FRAC 7+11	FRAC 1	FRAC 9+3	FRAC 7+11	
			or	or		or	
			FRAC 19	FRAC 3		FRAC 1	

Spray different fungicides at different timings in following season

Factors that might affect efficacy of preharvest fungicides

- **Rain:** Late cultivars
- **Overhead irrigation**
- **Rate:** low vs. high label rate
 - Use higher label rate: better control
- Fungicide **resistance**: Module 3

Harvest at commercial maturity: Over-mature fruit are more susceptible to decays

Postharvest Management

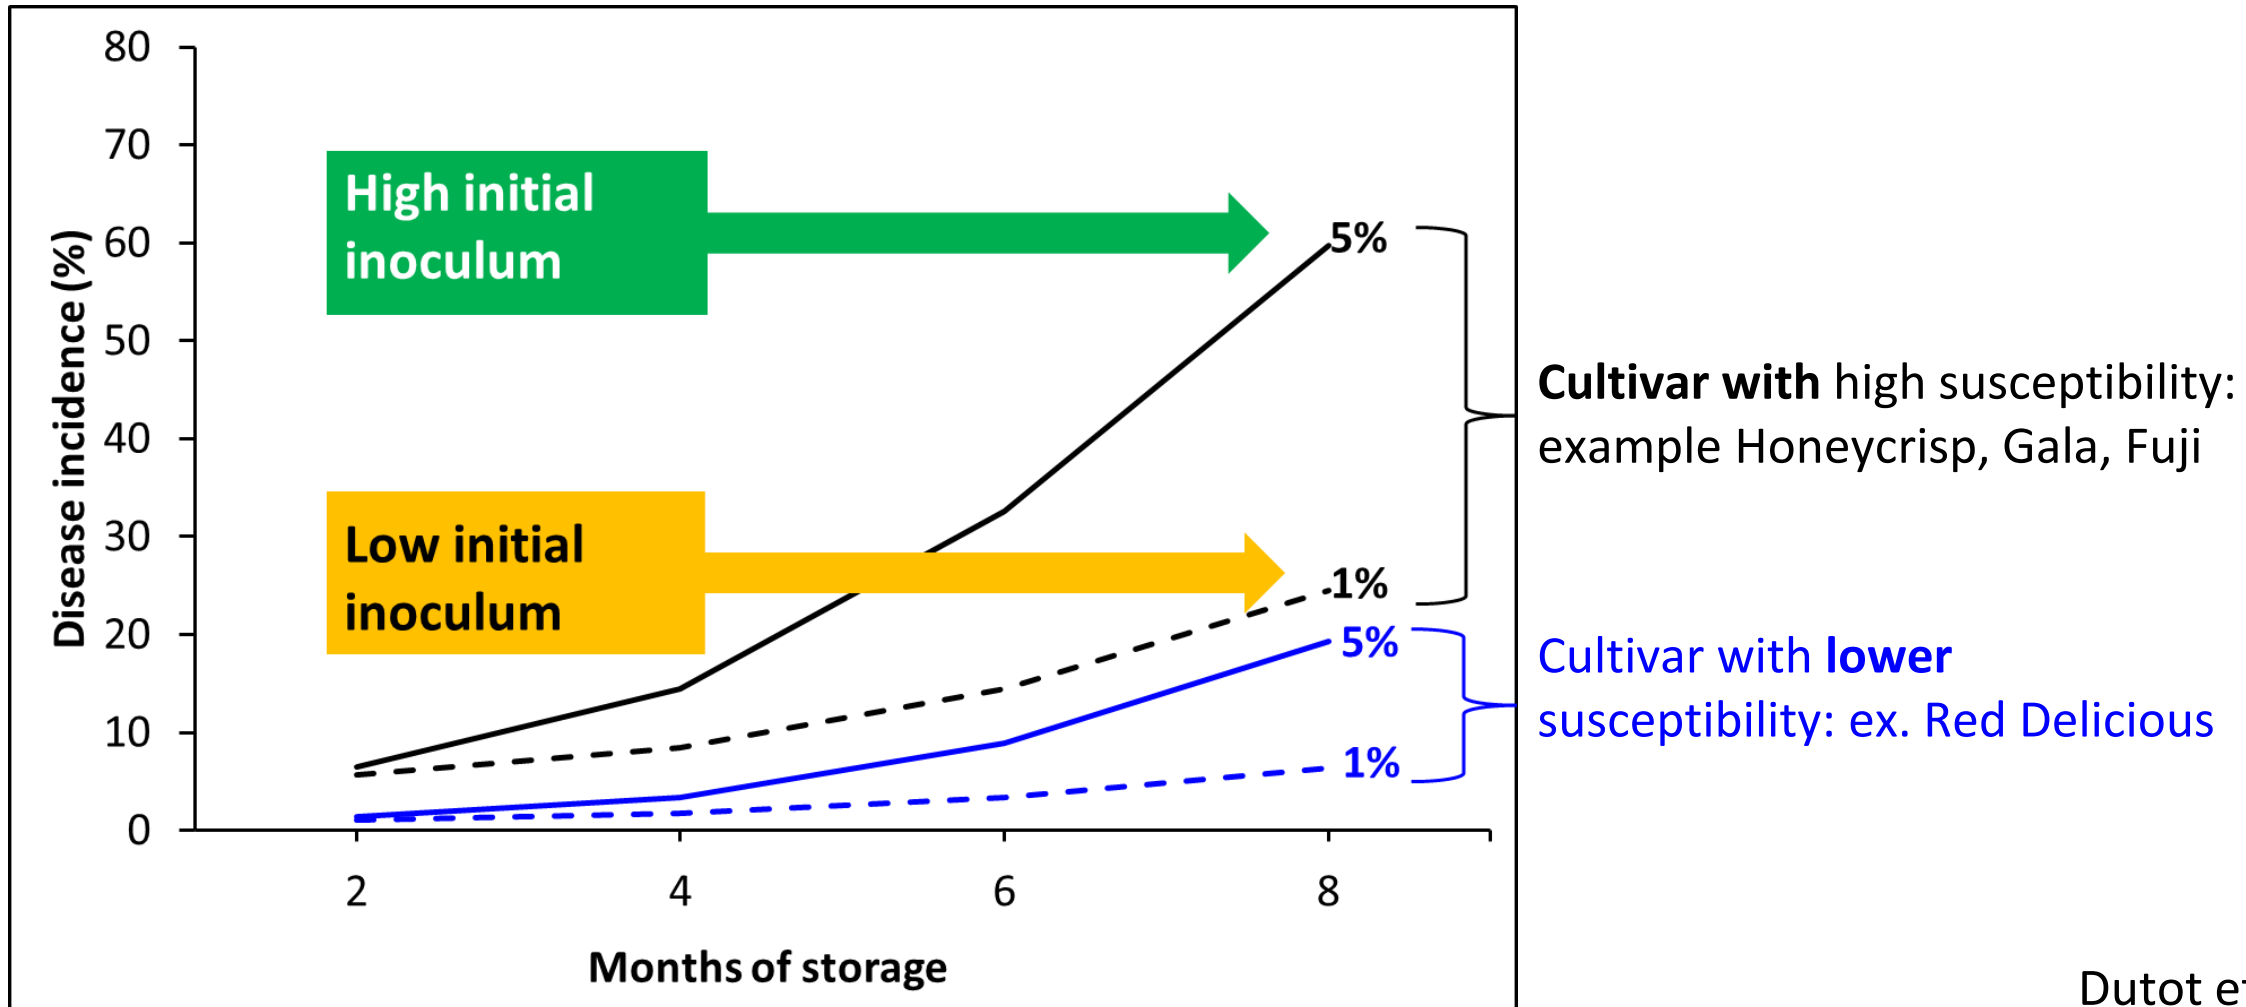

1. Do fruit infections stop after harvest ?
2. How to better prepare for the storage season?
3. Which fungicide works better and how to apply it?

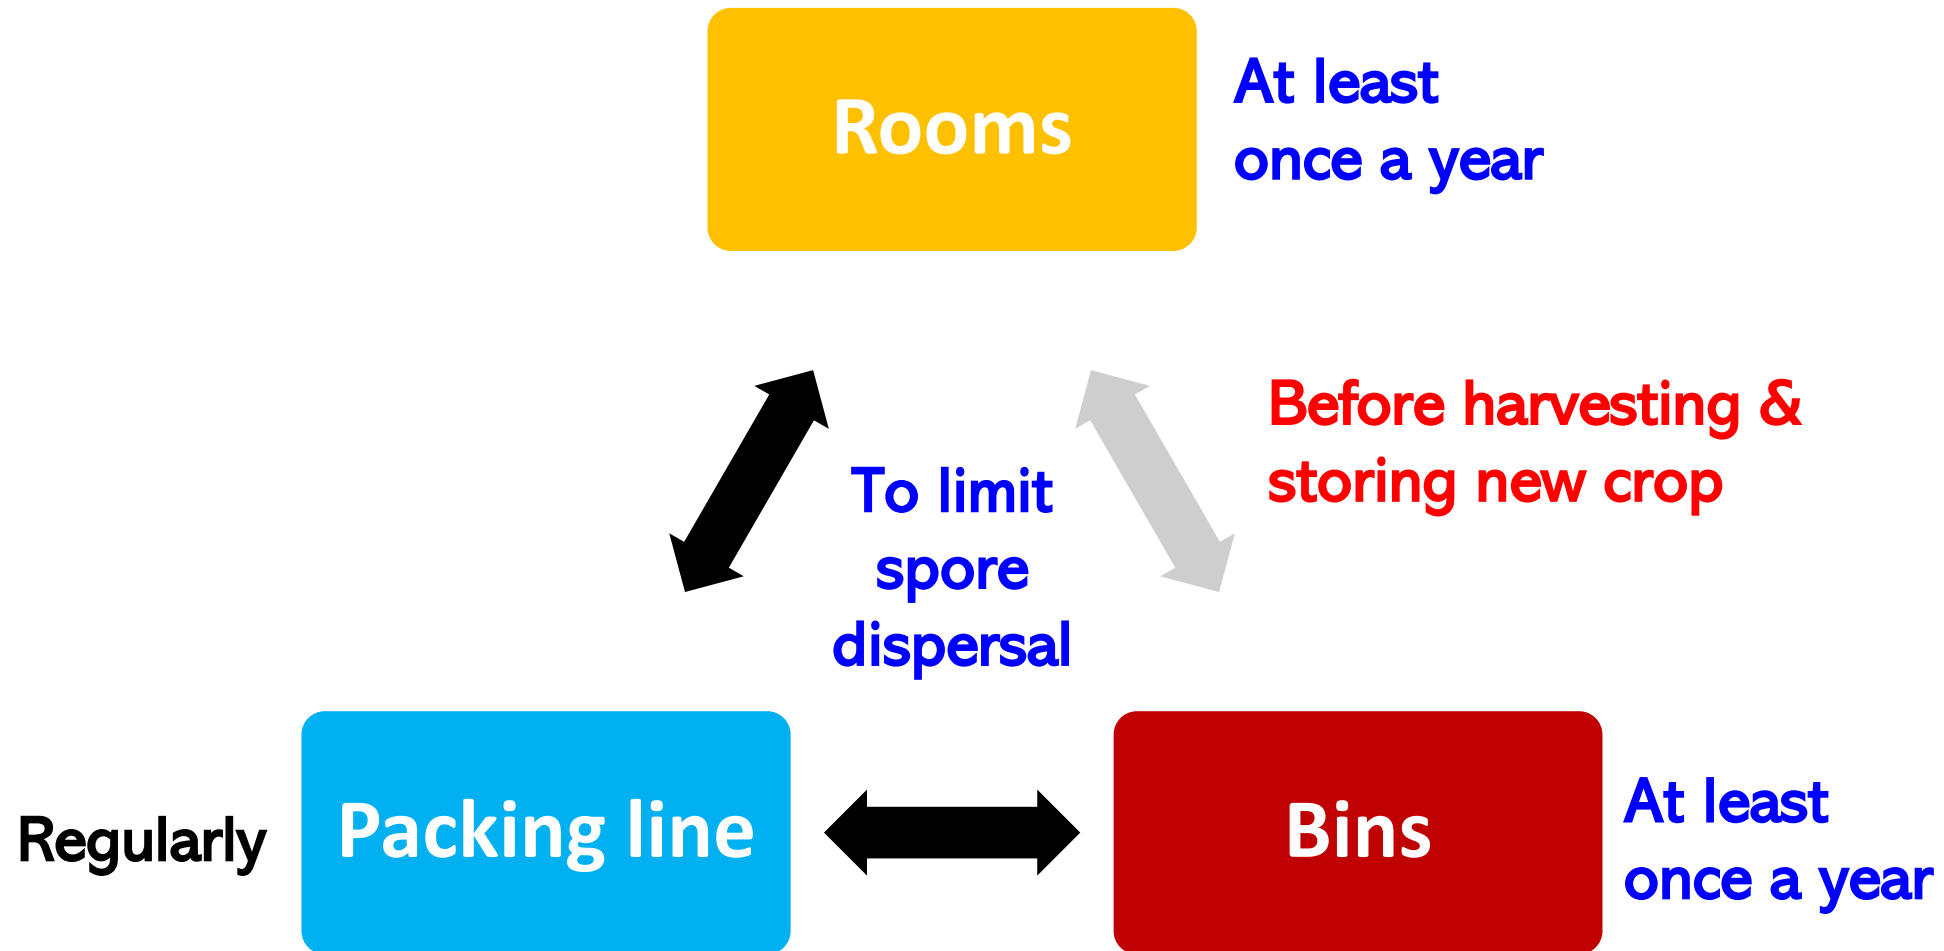

1. Do fruit infections stop after harvest ?
Module I-Part 2
 - Infections by field pathogens stop but decay may start developing in storage.
 - Infections by blue mold and Mucor rot start at harvest and continue during storage and packing.

Why is postharvest sanitation important to fight decays?

Inoculum size at beginning of storage is critical

Preparation for the storage season: Cleaning and Sanitation

Cleaning and Sanitation

Major pathogens of concern: *Penicillium* (blue mold), *Mucor* & *Cladosporium* (secondary)

Others: Spores of *Neofabraea* (bull's eye rot) and *Botrytis* (gray mold) found on bins

Rotten fruit touching bin sides

Abundant spores released to air and walls

Fully decayed fruit in bins: Cleaning a must

A. Amiri-WSU TFREC

Photos are subject to copyright

Airborne spores trapped from airs of storage rooms

Cleaning and Sanitation Bins

Photos are
subject to
copyright

- Wash bins after dump-tank
- Pressurized hot water
- Ozone fog?
- Hot summer may kill spores
- Brush underside bins before stacking or immersing in water

Cleaning and Sanitation Rooms

Photos are
subject to
copyright

- **Spores move: Remove decayed fruit inside & outside of rooms**
- **Wash walls and floors: detergent & sanitizer**
- **Gas/Fog: Ozone or PAA?**
- **Clean closer to harvest: avoid re-contaminations**

Preparation for the storage season: Cleaning and Sanitation

Sanitizer	Trade name ¹	Effective dose ²	Efficacy against <i>Penicillium</i> ³	
			Exposure time	Spore kill%
Quaternary Ammonium Compounds	Multiple	2-8 ml/L	3-10 min	• 87-97

pH will impact

Closed doors=foam

Pay attention to pH (read labels)

Pre-sizing: Apples

1. Storing wet fruit in cold storage for months
2. Provides additional moisture to fungi
3. Possible recontaminations in flume water
4. Apply a fungicide on the line?

Pre-packed pears

Pre-packing: Pears

1. Fruit sized and treated with a fungicides
2. Possible recontaminations in flume water
3. Stored in card-boxes and foils that may create generate moisture
4. **Repack if decay is $>2\%$**

Postharvest fungicides

1. Which fungicide works better ?
2. Is there a better method to apply fungicides?

Known efficacy* of current postharvest fungicides

Module II

Fungicide Resistance: Development & Mitigation

Learning Objectives

- **Better understand** fungicide resistance
- Fungicide resistance occurrence in the PNW
- **Reasons** behind resistance development
- Conduct risk assessment
- **Prevent & Mitigate** fungicide resistance

As a grower or a packer,
should I really **worry**
about **fungicide**
resistance when I
develop my spray
program?

Question

Is fungicide resistance caused by the:

- ☐ Fungicide? ✓
- ☐ Pathogen? ✓

Fungicide resistance can be defined as **the evolution** (change in genome) of the **pathogen population** caused by the fungicide selection pressure

Mode of action vs. site of action

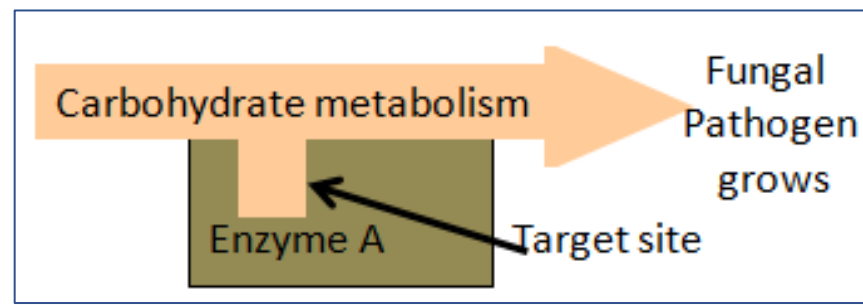

Mode of action of fungicides:
Respiration, reproduction, etc

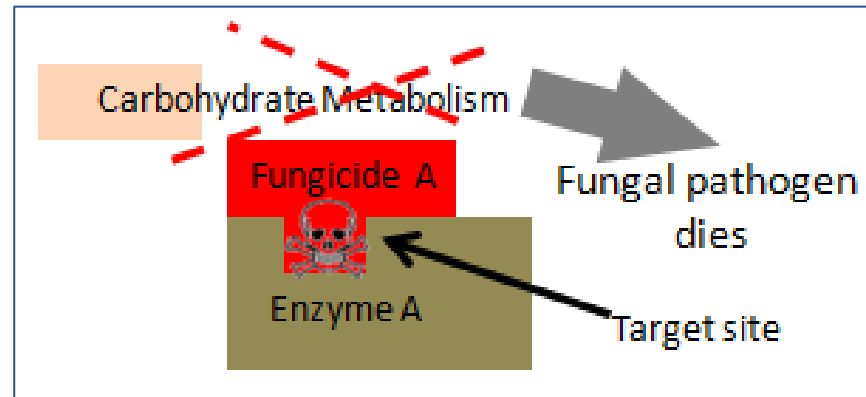

Site of action of fungicides:

- Multi-sites: Target Several sites
- Single-site: Target One site
- Example: Pristine and Merivon have the same site of action = potential cross-resistance
- Single-sites are at risk for fungicide resistance

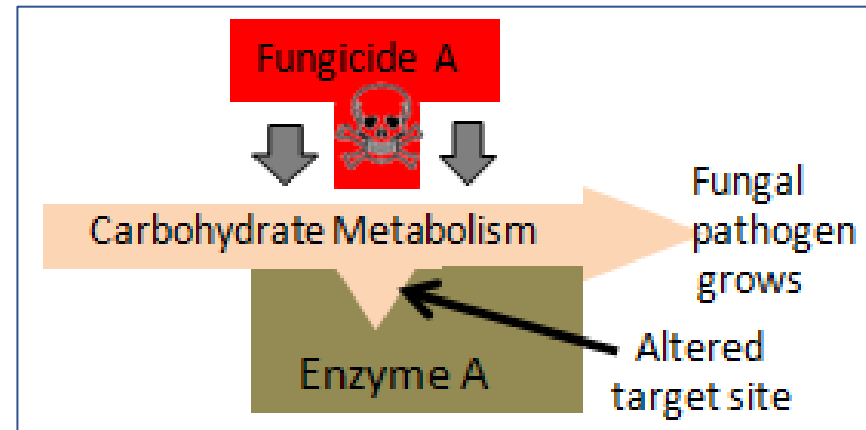

Sensitive fungus
Fungicide not applied

Sensitive fungus
Fungicide applied

Resistant fungus
Fungicide applied

Status of fungicide resistance in the PNW

Disease name	Pathogen name	Resistance status in the PNW
1. Gray mold	<i>Botrytis cinerea</i>	Documented
2. Blue mold	<i>Penicillium expansum</i>	Documented
3. Bull's eye rot	<i>Neofabraea</i> spp.	Suspected (FRAC1)
4. Alternaria rot	<i>Alternaria alternata</i>	Suspected
5. Speck rot	<i>Phacidiopycnis</i> spp.	Unknown
6. Sphaeropsis rot	<i>Sphaeropsis pyriputrescens</i>	Unknown
7. Yellow rot	<i>Lambertella corni-marais</i>	Unknown
8. Mucor rot	<i>Mucor piriformis</i>	N/A

Questions

I have resistance to TBZ in my warehouse:

- ☐ No worry; I still have Scholar and Penbotec
- ☐ I need to know **more** before I start worrying? ✓

What else do I have to consider?

- ☐ Resistance to other fungicides ✓
- ☐ Multiple*-resistance to other fungicides? ✓

* Multiple-resistance = strains resistant to more than 1 fungicide at a time

Example: Blue *mold-Penicillium* resistance 2016-17- Washington State
2,000 strains screened

Similar situation for gray mold

Impact

How is this knowledge beneficial for decay control?

- Most growers and packers in PNW have **low to moderate** fungicide resistance risk
- **Most trains** are either sensitive to all fungicides or resistant to one fungicide at time
- **Opens room for rotation of fungicides from different FRACs**
- **BUT 20-30% of growers/packers in PNW are at higher risks: need to implement drastic changes**

Source(s) and path of resistant populations

We may not spray frequently but the **exposure time** in pome fruit is longer than in any other system

Fungicide Resistance Mitigation

Proactive Fungicide Resistance Avoidance

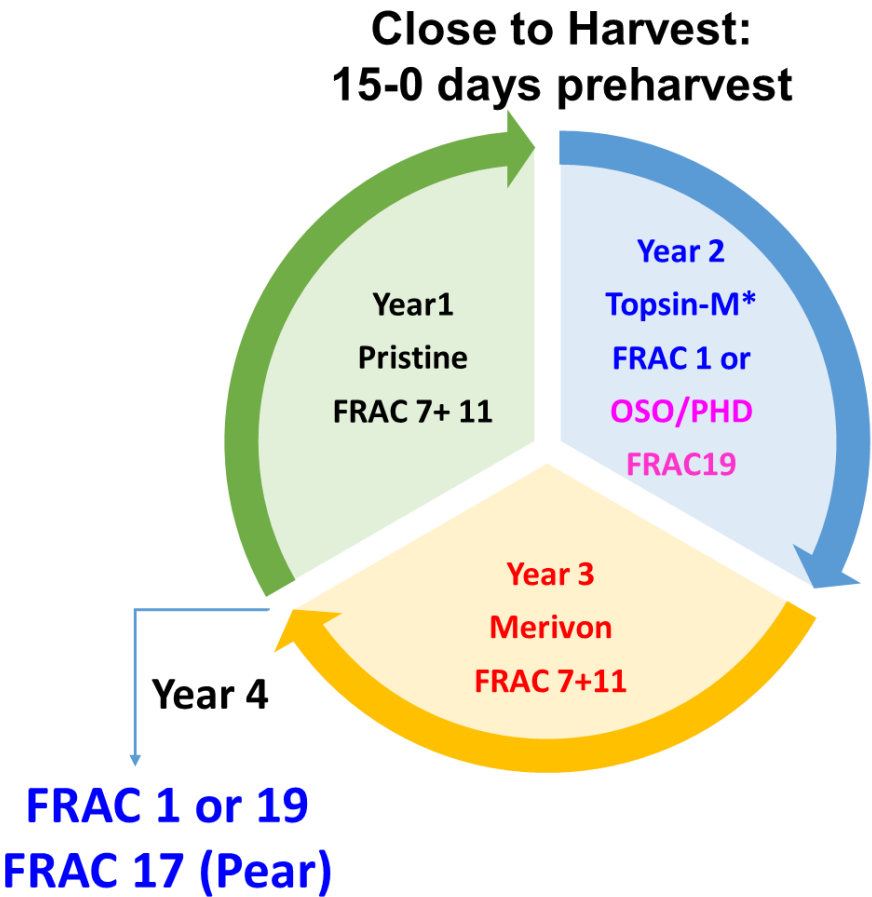

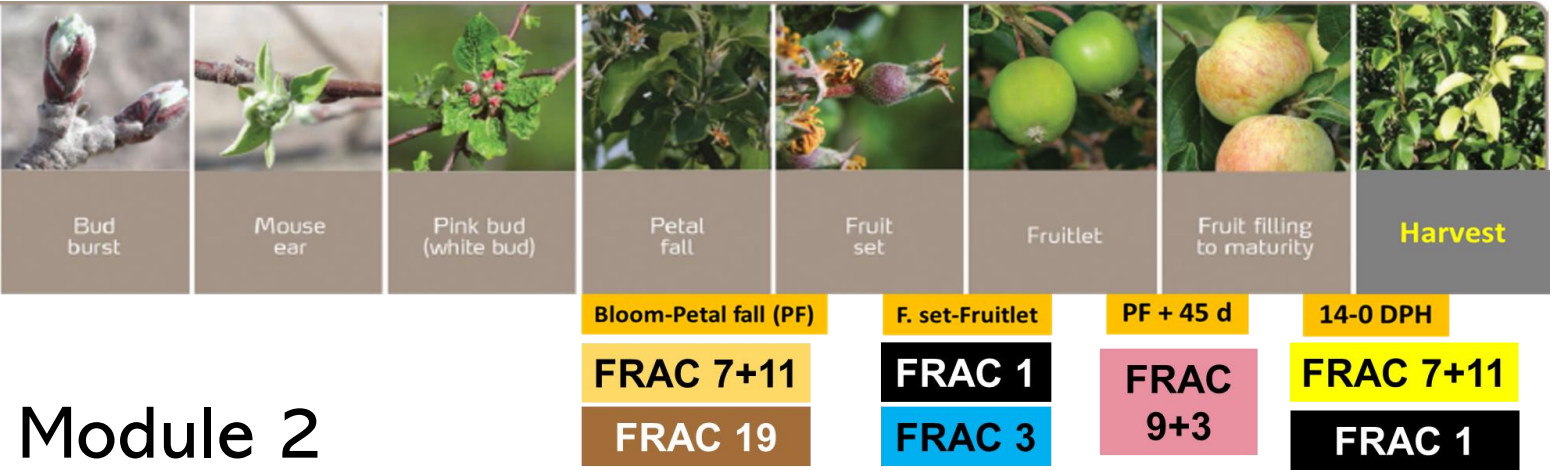

- It takes on average 10 years to develop and register a fungicide
- More challenging to register new **postharvest** fungicides
- Best strategies should start **upon registration** to extend fungicide lifespan

Cultural Practices: Sanitation to lower inoculum load: **HUGE impact**

- *Botrytis* is a latent (dormant) pathogen: the cleaner the fruit at harvest the lower the gray mold risk in storage
- Remove all potential sources of inoculum: Mummies, litter, weeds
- Avoid excess of overhead cooling/irrigation
- Spray timely: 7 days preharvest may not eliminate latent infections (Module 2)

Rotation of fungicides in the Orchard

The case of FRAC 7 fungicides and *Botrytis*: Cross-Resistance

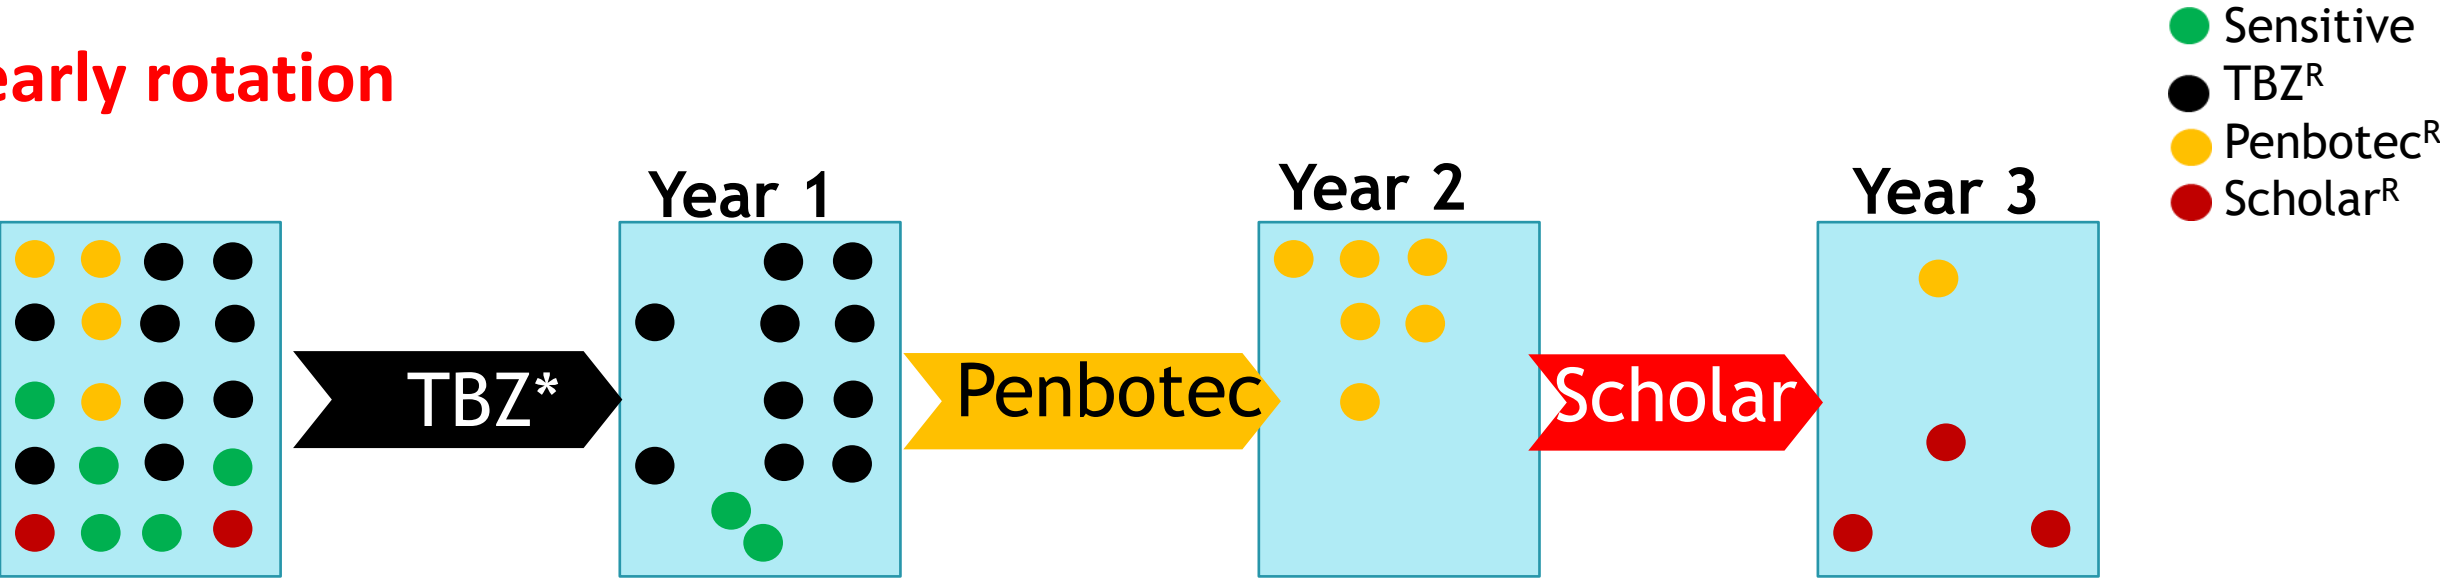

If Resistant to 	Luna	Fontelis	Aprovia	Merivon	Pristine
Luna-R	R	R	R	R	R
Fontelis-R	S	R	R	R	R
Aprovia-R	S	R	R	R	R
Merivon-R	S	R	R	R	R
Pristine-R	S	S/R*	S/R	S/R	R

* Some mutations confer resistance, others not

If Luna products are over-sprayed **early season**, they may select for resistant populations that **will not be controlled** by **any other FRAC 7**

Rotation (Alternation) of fungicides: Pre- and Postharvest

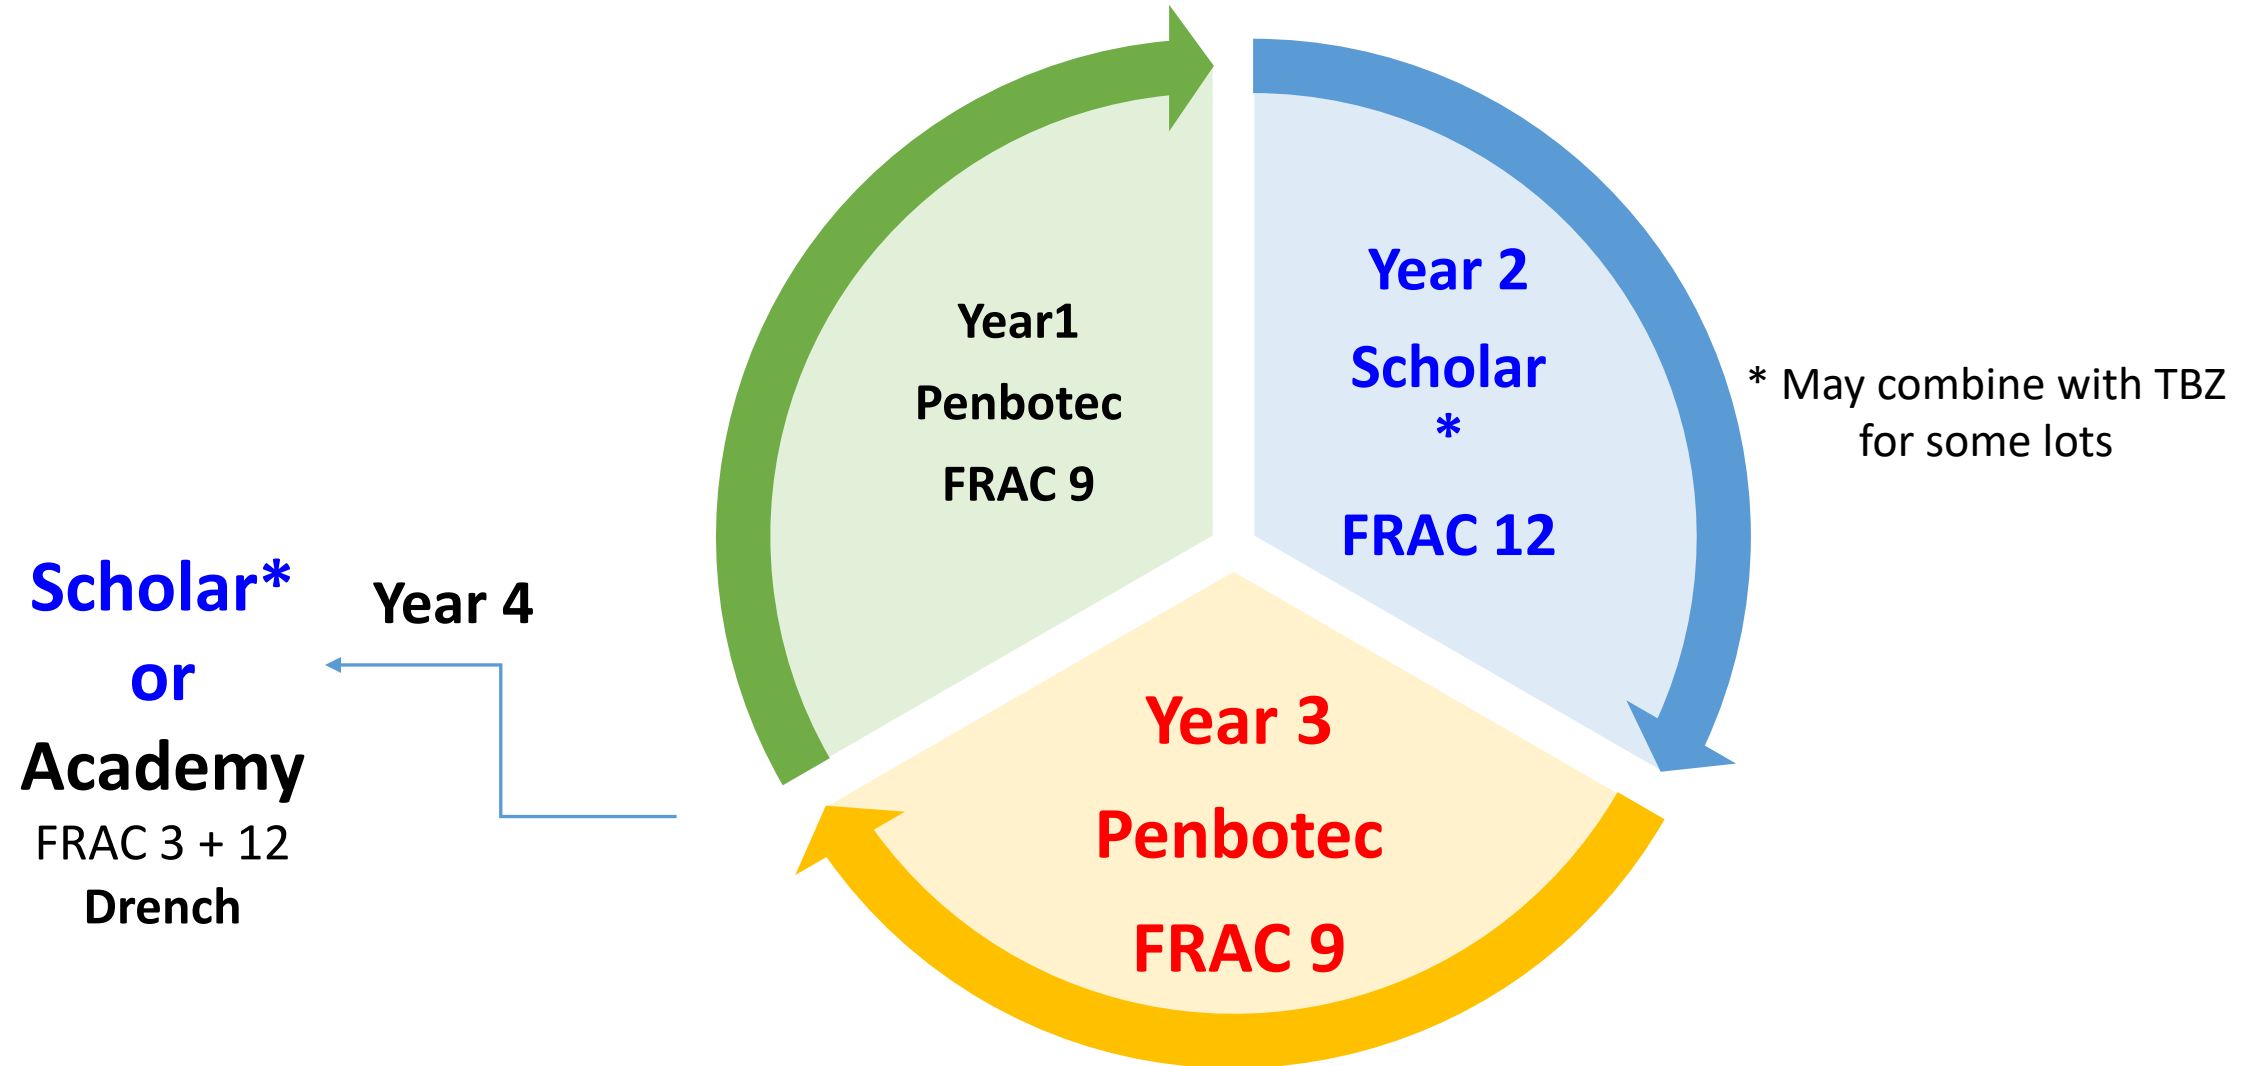

Yearly rotation

2 Years rotation

Rotation of postharvest fungicides

Label rate

High vs. low

Is there a real risk?

- Low label rate:
 - Fungus may adapt
 - Develop tolerance or reduced sensitivity
- Use higher label rate:
 - Better control
 - Reduces inoculum (sanitation)
- Postharvest:
 - Dry application may result in variable residue levels within the room
 - Effect unknown

Summary

- Fungicide resistance has developed/emerged in the PNW
- Overall Resistance frequencies are low to moderate:
Mitigation options available
- 20-30% growers/packers need to implement drastic changes to avoid total control failure
- **Be proactive**, act upon registration, and consider fungicides as YOURS
- Sanitation: lower exposure = lower risk
- Contact us if you need help to profile your locations
